#### **Project aims:**

- Build a Bayesian hierarchical model to predict football results in the Premier League
- Implement the model using Hamiltonian Monte Carlo with the Stan programming language and R
- Look at different techniques to assess model performance and compare with Baio & Blangiardo's model (2010)

| TL. N.       |                         |  |                  |            |

| Introduction | Negative Binomial Model | Results from the Negative Binomial model | Model Assessment | Discussion |

- Here, we use the negative binomial distribution to model the number of goals scored by the home and away team.
- The use of the negative binomial distribution in football models have been largely ignored.
- Generally, an independent Poisson distribution is used to model the number of goals scored by each team.
- We use the parametrisation that Stan uses in terms of the mean μ and size n, which has the probability mass function:

| Introduction | Negative Binomial Model | Results from the Negative Binomial model | Model Assessment | Discussion |

- Let  $y_{g1}$  and  $y_{g2}$  denote the number of goals scored by the home and away team in the *g*-th game of the season, respectively.
- We believe these follow a negative binomial distribution, with mean  $\mu_{gj}$  and size  $n_j$ , where j = 1 for the home goals and j = 2 for the away goals:

| Introduction<br>0 | Negative Binomial Model<br>0●0000 | Results from the Negative Binomial model | Model Assessment | Discussion<br>0000 |
|-------------------|-----------------------------------|--|------------------|--------------------|
| TTI NI            | D'                                | • I N A I I                              |                  |                    |

- Let  $y_{g1}$  and  $y_{g2}$  denote the number of goals scored by the home and away team in the *g*-th game of the season, respectively.
- We believe these follow a negative binomial distribution, with mean  $\mu_{gj}$  and size  $n_j$ , where j = 1 for the home goals and j = 2 for the away goals:

$$y_{gj} \mid \mu_{gj}, n_j \sim \mathsf{NB}(\mu_{gj}, n_j),$$

where  $\mu_{gj}$  represents the mean number of goals expected to be scored by the home team (j = 1) and the away team (j = 2) in the *g*-th game of the season.

## The Negative Binomial Model - Results

• We use the data from the 2017/18 Premier League season, to obtain estimates for the attack and defence parameters for each team.

• The data is taken from the the football-data.co.uk website

#### The Negative Binomial Model - Results

• We use the data from the 2017/18 Premier League season, to obtain estimates for the attack and defence parameters for each team.

- The data is taken from the the football-data.co.uk website
- Higher attack parameter  $\implies$  better attacking ability.
- Higher defence parameter  $\implies$  worse defending ability.

Using this model for prediction of football matches, we can obtain posterior probabilities for:

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- match outcomes (home win / draw / away win),
- final scores.

Using this model for prediction of football matches, we can obtain posterior probabilities for:

- match outcomes (home win / draw / away win),
- final scores.

After using the Stan programming language and R to implement the model, we obtain a sample from our target density. Once we have a sample from our posterior distribution, we can draw from a predictive distribution of unobserved data or future data.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

In our case, to predict a football match between team A (playing at home) vs. team B (playing away):

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

In our case, to predict a football match between team A (playing at home) vs. team B (playing away):

• Extract the samples for the attack and defence parameters for each team and for the size  $n_j$ , for j = 1, 2.

In our case, to predict a football match between team A (playing at home) vs. team B (playing away):

- Extract the samples for the attack and defence parameters for each team and for the size  $n_j$ , for j = 1, 2.
- 2 Use the formula for  $\mu_j$ , j = 1, 2, to get

 $\log \mu_1 = home\_att_A + away\_def_B,$  $\log \mu_2 = away\_att_B + home\_def_A.$ 

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

In our case, to predict a football match between team A (playing at home) vs. team B (playing away):

- Extract the samples for the attack and defence parameters for each team and for the size  $n_j$ , for j = 1, 2.
- 2 Use the formula for  $\mu_j$ , j = 1, 2, to get

 $\log \mu_1 = home\_att_A + away\_def_B,$  $\log \mu_2 = away\_att_B + home\_def_A.$ 

 Obtain draws from our likelihood, π(y<sub>j</sub><sup>\*</sup> | μ<sub>j</sub>, n<sub>j</sub>), for j = 1,2, (from a negative binomial distribution).

In our case, to predict a football match between team A (playing at home) vs. team B (playing away):

- Extract the samples for the attack and defence parameters for each team and for the size  $n_j$ , for j = 1, 2.
- 2 Use the formula for  $\mu_j$ , j = 1, 2, to get

 $\log \mu_1 = home\_att_A + away\_def_B,$  $\log \mu_2 = away\_att_B + home\_def_A.$ 

- Obtain draws from our likelihood, π(y<sub>j</sub><sup>\*</sup> | μ<sub>j</sub>, n<sub>j</sub>), for j = 1,2, (from a negative binomial distribution).
- Now we have a sample from the predictive distribution for number of goals scored by each team, and we can use these for prediction.

The scoring rules that were used to assess the model's performance for the prediction of football scores were:

- Cross-Validation
- The Brier score
- The rank probability score

Additionally, we assessed the model's performance by attempting to predict a league table using the model and using it as a basis of a betting model.

#### Model Assessment - results and comparison

We calculate the cross-validation score, Brier score, rank probability score and the profit/loss from betting £10 on the most probable outcome for the two models for the 2017/18 Premier League season.

| Model | Cross-Validation | Brier score | Average RPS | Profit/Loss |
|-------|------------------|-------------|-------------|-------------|
| BB    | 57.8%            | 0.532       | 0.173       | £449.9      |
| NB    | 59.7%            | 0.540       | 0.177       | £873.3      |

- By simply just using previous goals data, we are able to achieve a good model for prediction of football matches.
- By assessing the model's usefulness as a basis of a decision rule for betting, it was able to turn a profit has real world applications.
- By splitting up the attack and defence parameters for home and away and not using a constant home-advantage parameter as Baio & Blangiardo (2010), Dixon & Coles (1997), Lee (1997), Maher (1982), we are able to encode more information on each team's performances.

• Although the model was able to turn a profit, there was still 149 games that the model incorrectly predicted the outcome of the game ( $\approx 40.3\%$ ), so there is still a lot of room for improvement.

- Discussion weaknesses
  - Although the model was able to turn a profit, there was still 149 games that the model incorrectly predicted the outcome of the game ( $\approx 40.3\%$ ), so there is still a lot of room for improvement.
  - The model only uses goals to obtain estimates for parameters for each team.
    - Goals may not the best indicator for how well a team is performing teams can be lucky or unlucky.
    - Possibly by incorporating more data, we can obtain more accurate estimates for the attack and defence parameters for each team.

- Discussion weaknesses
  - Although the model was able to turn a profit, there was still 149 games that the model incorrectly predicted the outcome of the game ( $\approx 40.3\%$ ), so there is still a lot of room for improvement.
  - The model only uses goals to obtain estimates for parameters for each team.
    - Goals may not the best indicator for how well a team is performing teams can be lucky or unlucky.
    - Possibly by incorporating more data, we can obtain more accurate estimates for the attack and defence parameters for each team.
  - Model ignores other possible factors that can affect team performance, for example:
    - injury/resting of star players
    - fatigue of players / number of days rest between games

|---------|-------------------------|--|------------------|--------------------|--|--|--|--|
| Summary |                         |  |                  |                    |  |  |  |  |

- We built a Bayesian hierarchical model for prediction of football results, which used a negative binomial distribution to model the goals scored by each team.
- By using several techniques for model assessment, there was not much difference between the negative binomial model and Baio & Blangiardo's model.
  - But the model was far superior when using it as a basis for a betting decision rule and gave a much higher profit return.
